<sup>[2]</sup> Professor, Institute of Engineering and Technology, Lucknow.

**Abstract:** Flat slab system is a construction in which beams are not used as in the case of conventional slabs. In such way the economy of project, architectural appearance, speed of construction, less weight of super structure are the advantages possessed by a flat slab over a conventional RC framed structure. However, because of no use of beams in flat slab the lateral stiffness is reduced which effects the overall performance of flat slab when subjected to seismic excitation. In the present study, two different types of slabs namely conventional and flat slabs were taken in a G+15 multistorey building and the seismic behaviour of the two systems were compared in seismic zone IV. The analysis was done using elastic time history method analysis in ETABS2016 software according to rules and regulations of Indian standard code.

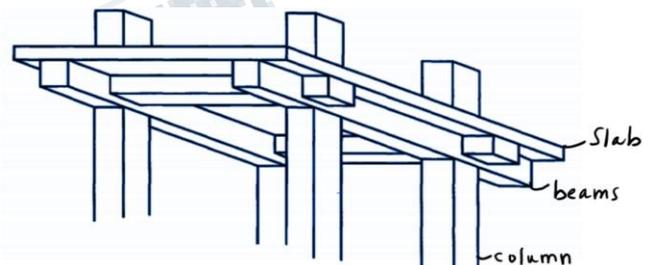

**Keywords:** conventional slab, flat slab, RC building, time history method, story drift, displacement, time period and base shear.

## INTRODUCTION

Earthquake resistant design of RC buildings has been a much widely researched area since the development of earthquake engineering. Recently the earthquakes occurring have resulted in huge loss of life and property and hence the requirement of such structures has arisen which are resistant to earthquake or result in least amount of destruction. Seismic determination of high rise multi story building is very important in order to analyze the response of structure subjected to earthquake. For a developing country like India, steel reserves are still not adequate and hence raw material for RC concreting are highly being used as it also results in lower cost and less skilled labour are required. The conventional slab system and flat slab system behave differently when subjected to earthquake excitation. Therefore, seismic analysis of their behavior becomes very necessary.

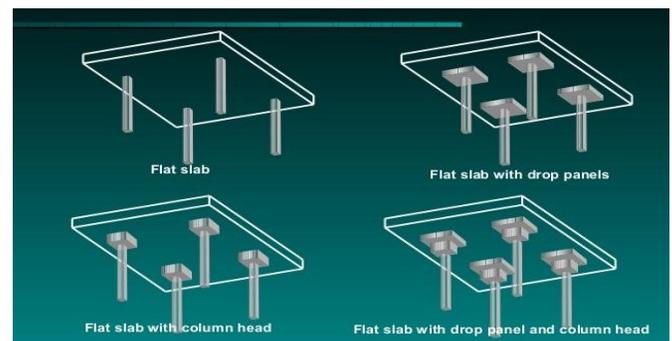

Flat slab is a beamless slab with or without drops supported by columns with or without flare heads unlike the conventional slabs system where the beams are used. The load is transferred in flat slab from slab to columns and then directly to the footing. In order to provide additional shear strength and to reduce the amount of negative reinforcement in support region, the flat slabs are usually thickened near columns. Flat slabs are provided in malls, theatres and other structures where large beam and free spaces are required. Generally shear walls are required when earthquake resistance is considered. Such slabs can be designed to resist both vertical and lateral loads in low seismicity zone (zone II) however for high seismicity (zone III, IV, V) code does not permit flat slab construction without any resisting system or lateral force resisting system.

In case of conventional slabs, the load from slabs is first transferred to beams and then to columns and hence the weight of structure increases and the formwork is also costly and complicated when compared to flat slab structures. In these kind of slabs, the thickness of slab is small whereas depth of beam is large and hence more formwork is needed as compared to that of flat slabs. In this type of slab the dead load is more than flat slab and also there is extra requirement of flat attractive appearance of ceilings.

**2. STRUCTURAL DETAILS**

In the present study three models were generated by using ETABS software. All the models were analyzed in seismic zone IV in a G+15 multistory building by using elastic time history method analysis.

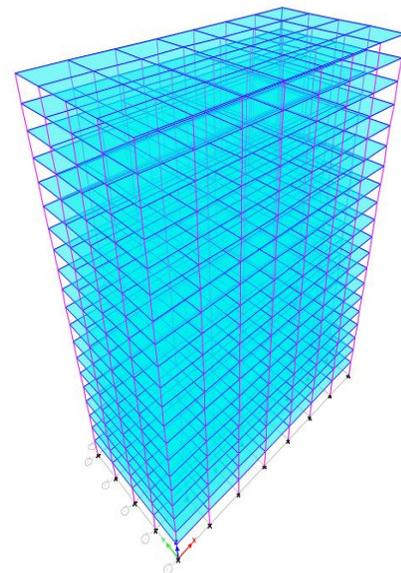

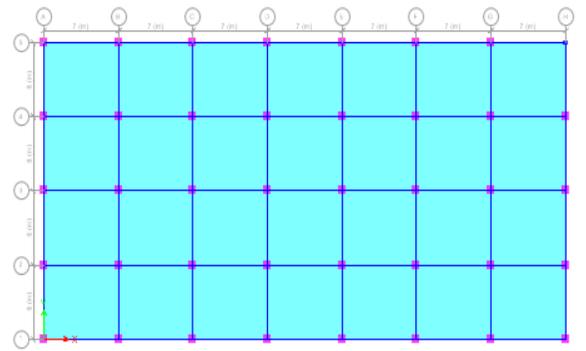

- MODEL 1- CONVENTIONAL SLAB
- MODEL 2- FLAT SLAB
- MODEL 3- FLAT SLAB WITH SHEAR WALL.

Structural data is as follows:

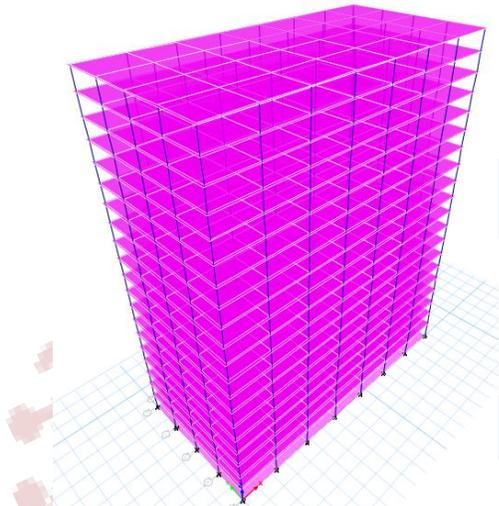

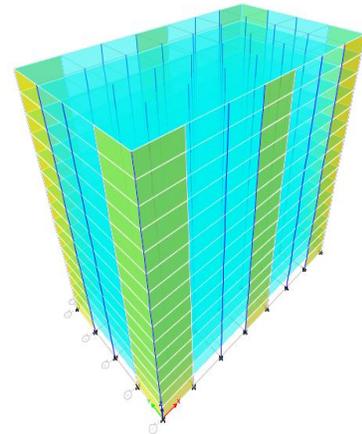

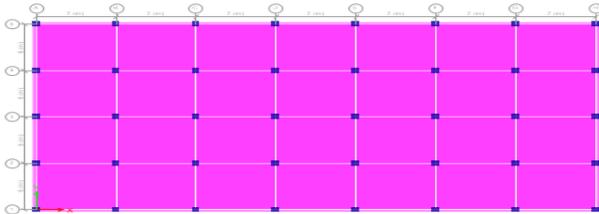

|    |                                      |                     |
|----|--------------------------------------|---------------------|
| 1  | Building type                        | Commercial building |
| 2  | Plan dimensions                      | 49X28m (X*Y)        |
| 3  | No. of stories                       | G+15                |
| 4  | Floor to floor height                | 3m                  |
| 5  | Total height of building             | 45m                 |
| 6  | Slab thickness for conventional slab | 150mm               |
| 7  | Slab thickness for flat slab         | 180mm               |
| 8  | Thickness of shear wall              | 200mm               |
| 9  | Column size                          | 600x600mm           |
| 10 | Beam size                            | 500x250mm           |
| 11 | Live loads                           | 3 KN/m <sup>2</sup> |
| 12 | Seismic zone                         | IV                  |
| 13 | Importance factor                    | 1.5                 |
| 14 | Soil type                            | IV                  |
| 15 | Grade of concrete(slab, beam)        | M 30                |
| 16 | Grade of concrete(column)            | M 35                |
| 17 | Reinforcement                        | Fe415               |

**TABLE 1.1**

The plan view and the 3 dimensional view of the models have been shown as follows:

**Fig 1.3- Plan and 3d view of conventional slab**

**Fig 1.4- Plan and 3d view of flat slab without shear wall**

**Fig 1.5- Plan and 3d view of flat slab with shear wall**

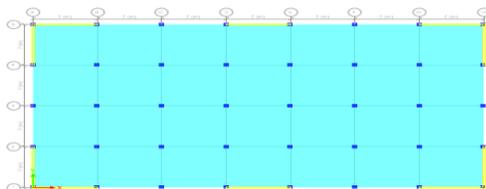

**3) RESULT AND DISCUSSION:**

In this section, the results obtained from all the three models analyzed by using ETABS software have been mentioned for various parameters like story drift, story displacement, time period and base shear.

**3.1) STORY DRIFT:**

Story drift can be understood as the difference between one story with respect to the other story. It is an important criteria which depicts the performance of structure as per IS 1893:2002 part 1, clause 7.11.1; story drift should be less than 0.004 times the height of the story under consideration. In this case it should be less than 12.

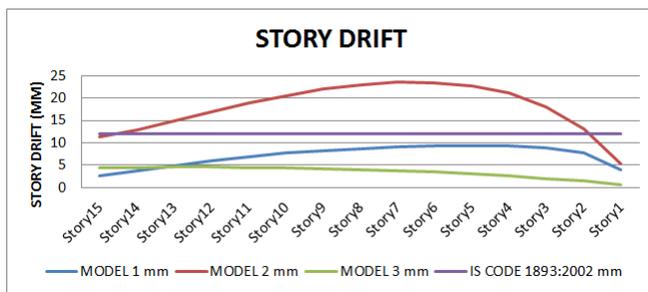

| Story   | MODEL 1 | MODEL 2 | MODEL 3 | IS CODE 1893:2002 |
|---------|---------|---------|---------|-------------------|
|         | mm      | mm      | mm      | mm                |
| Story15 | 2.698   | 11.241  | 4.455   | 12                |
| Story14 | 3.804   | 12.822  | 4.52    | 12                |
| Story13 | 4.962   | 14.813  | 4.553   | 12                |
| Story12 | 6.012   | 16.891  | 4.553   | 12                |
| Story11 | 6.912   | 18.854  | 4.511   | 12                |
| Story10 | 7.657   | 20.576  | 4.42    | 12                |
| Story9  | 8.258   | 21.971  | 4.274   | 12                |

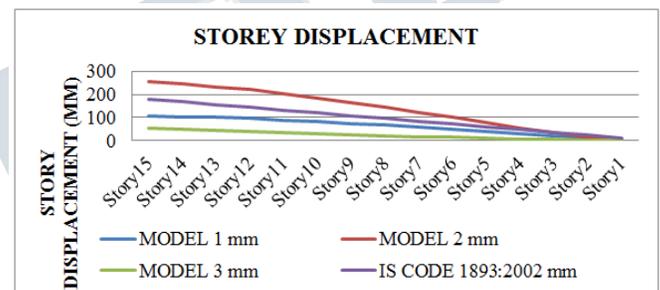

|        |       |        |       |    |
|--------|-------|--------|-------|----|
| Story8 | 8.724 | 22.972 | 4.069 | 12 |
| Story7 | 9.069 | 23.506 | 3.801 | 12 |
| Story6 | 9.3   | 23.476 | 3.469 | 12 |
| Story5 | 9.411 | 22.734 | 3.068 | 12 |
| Story4 | 9.356 | 21.043 | 2.599 | 12 |
| Story3 | 8.963 | 18.022 | 2.055 | 12 |
| Story2 | 7.693 | 13.07  | 1.444 | 12 |
| Story1 | 3.87  | 5.196  | 0.704 | 12 |

**Table 1.2**

|         |        |         |        |     |
|---------|--------|---------|--------|-----|
| Story10 | 82.106 | 185.942 | 29.902 | 120 |
| Story9  | 74.467 | 166.204 | 25.482 | 108 |

**Fig 1.6**

**Fig 1.7**

### 3.2) STORY DISPLACEMENT:

Story displacement is an important criterion when structures are subjected to lateral loads like earthquake and wind loads. Height of structure and slenderness of the structure are important factors for determining story displacement because structures are more vulnerable as height of building increases by becoming more flexible to lateral loads. The displacement is maximum at top and bottom at base of structure. According to IS 1893:2002; maximum allowable deflection is calculated as  $h/250$ , where  $h$  is the height of the storey from the ground level.

| Story   | MODEL 1 | MODEL 2 | MODEL 3 | IS CODE 1893:2002 |
|---------|---------|---------|---------|-------------------|
|         | mm      | mm      | mm      | mm                |
| Story15 | 106.438 | 256.529 | 52.494  | 180               |
| Story14 | 103.745 | 246.069 | 48.038  | 168               |
| Story13 | 99.949  | 234.04  | 43.519  | 156               |
| Story12 | 94.998  | 220.034 | 38.966  | 144               |
| Story11 | 89.001  | 203.964 | 34.413  | 132               |

### 3.3) TIME PERIOD:

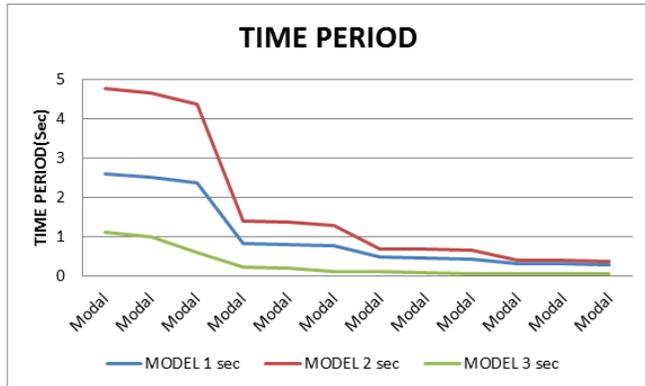

Greater the time period the more flexible is the structure or lesser the time period more rigid the structure. Time period has been calculated in the following table for seismic zone IV.

| Case  | MODEL 1 | MODEL 2 | MODEL 3 |
|-------|---------|---------|---------|
|       | sec     | sec     | sec     |
| Modal | 2.59    | 4.756   | 1.124   |
| Modal | 2.503   | 4.657   | 0.992   |
| Modal | 2.372   | 4.361   | 0.597   |
| Modal | 0.838   | 1.407   | 0.235   |
| Modal | 0.812   | 1.384   | 0.202   |
| Modal | 0.768   | 1.297   | 0.128   |

*Table 1.5*

*Fig 1.8*

*Fig 1.9*

**3.4) BASE SHEAR:**

Base shear calculation depicts the automatically generated lateral seismic loads for load pattern EQ- X and EQ- Y according to IS1893:2002.

| Story   | MODEL 1  | MODEL 2  | MODEL 3  |
|---------|----------|----------|----------|
|         | kN       | kN       | kN       |
| Story15 | 530.8352 | 224.4948 | 744.538  |
| Story14 | 486.7515 | 211.3627 | 757.1935 |
| Story13 | 419.699  | 182.2464 | 652.8862 |
| Story12 | 357.6133 | 155.2869 | 556.3054 |
| Story11 | 300.4945 | 130.4841 | 467.4511 |
| Story10 | 248.3426 | 107.8381 | 386.3232 |
| Story9  | 201.1575 | 87.3489  | 312.9218 |
| Story8  | 158.9393 | 69.0164  | 247.2469 |
| Story7  | 121.6879 | 52.8407  | 189.2984 |
| Story6  | 89.4033  | 38.8217  | 139.0764 |
| Story5  | 62.0856  | 26.9595  | 96.5808  |
| Story4  | 39.7348  | 17.2541  | 61.8117  |
| Story3  | 22.3508  | 9.7054   | 34.7691  |
| Story2  | 9.9337   | 4.3135   | 15.4529  |

**4) CONCLUSION:**

- With references to the output, story drift reduces after the addition of shear wall in flat slab building. Story drift in flat slab structures without placement of shear wall is more when compared to conventional slab hence stating the importance of shear wall.
- The story displacement increases with the height of the structure. The displacement is reduced by 70%-80% in case of flat slab with shear wall. It means after the addition of shear wall the flat slab building lateral deflection reduces due to increase in rigidity but in absence of shear wall the performance of conventional is better than flat slab.
- The natural time period is reduced to 75%-80% after the placing of shear wall. The conventional structure is less flexible than flat slab without shear wall.
- Base shear increases with increase in mass and stiffness of building and hence the base shear is maximum for flat slab with shear wall. 60%-70% increase in base shear is noticed when shear wall is added.
